

Localisation Pipeline

How an episode becomes nine episodes

Step one, transcription and timing

The source audio is transcribed and time aligned at the phrase level. A language lead corrects names, places and any dialect the model mishears, which for Malayalam source material is the single largest error class.

Step two, adaptation not translation

A writer adapts the script for length and lip closure rather than translating it literally. A line that is accurate but two syllables too long is a failed line.

Step three, synthesis

Voice models built from consented artist recordings generate the first pass. The director reviews every scene and marks the ones that need a human take.

Step four, the human pass

Typically 12 to 18 percent of runtime is re recorded by the artist. Arguments, crying, singing and anything with overlapping dialogue almost always go to a human.

Step five, mix and deliver

Dialogue is mixed back against the original music and effects stems, checked against the platform delivery specification, and shipped with subtitles in the same language.
